Federal Planning Bureau

The Federal Planning Bureau (FPB) is a public agency that carries out, in support of political decision-making, forecasts and studies on economic, social-economic and environmental policy issues and examines their integration into a context of sustainable development. It shares its expertise with the government, parliament, social partners, national and international institutions.

The FPB adopts an approach characterised by independence, transparency and the pursuit of the general interest. It uses high-quality data, scientific methods and empirical validation of analyses. The FPB publishes the results of its studies and, in this way, contributes to the democratic debate.

The Federal Planning Bureau is EMAS-certified and was awarded the Ecodynamic enterprise label (three stars) for its environmental policy.

Abstract - The supplementary table on pension schemes in social insurance, Table 29, is part of the Eurostat transmission program. The table reports the accrued-to-date pension entitlements/liabilities in social insurance. These entitlements represent accrued-to-date future pensions of current beneficiaries and future beneficiaries who already accumulated some career years. These entitlements do not represent public debt and are not an indicator of the financial sustainability of the pension system and are only appropriate for national accounts purposes. This report documents the methods, data sources and assumptions used in the compilation of the supplementary table. It is an update of the report on the first transmission in 2017 of Table 29 data for the year 2015.

Jel Classification - E01

Keywords - National accounts, Table 29, Supplementary table, Accrued-to-date liabilities, Pension entitlements, Eurostat

¹ This report draws heavily on the report on the first transmission in 2017 of Table 29 data by Yves Brys (Brys, 2017).

Executive summary

The supplementary table 29 of the Eurostat transmission program covers the statutory pensions and occupational pension schemes in social insurance in Belgium. It includes employment-related pension entitlements outside general government (2nd pillar pensions) and accrued-to-date pension entitlements/liabilities (ADL) to unfunded government pension schemes and social security pensions (1st pillar pensions) in Belgium. The National Accounts Institute is responsible for delivering this table to Eurostat. It has entrusted the National Bank of Belgium (NBB) and the Federal Planning Bureau (FPB) with the compilation of the supplementary table.

Table 29 is described by ESA 2010, the European System of Accounts 2010, and has as goal to establish a complete and consistent coverage of pension entitlements in a country and to promote comparability across countries. Therefore, the table brings together information already shown in the standard or 'core' national accounts (columns A to F of Table 29) with information on unfunded pension system (the statutory pension schemes), which are not reported in the core accounts (columns G and H of Table 29). The contribution of the FPB to Table 29 consists in compilation of columns G and H. Those columns include accrued-to-date pension entitlements/liabilities in the statutory pension scheme, representing the present discounted value of accrued-to-date future pensions of current beneficiaries and future beneficiaries who already accumulated some career years at the moment of evaluation. Pension benefits include old-age and survivors' pensions. Excluded are the social assistance schemes (guaranteed income for elderly and the guaranteed minimum income in social assistance), disability benefits and unemployment benefits with company allowance for non-job seekers, as well as benefits from individual insurance policies. Entitlements to employment-related complementary pensions (2nd pillar pensions) are recorded in other columns of Table 29.

The report comments on the assumptions of the modelling and the estimation methodology of the values. The values that are presented in this report are those that will be sent in the final transmission to Eurostat. The transmitted information will include Table 29, two alternative tables with a different discount rate and the fact sheets on the pension schemes as requested by Eurostat. This report represents an update of the Grant Report on the first submission of these Table 29 data, of October 2017 (Brys, 2017).

The projection of the ADL is very sensitive to the assumed discount rate. Following assumptions made by the Working Group on Ageing Populations and Sustainability (AWG) of the Economic Policy Committee of the EU Council for the 2021 Ageing Report, the long-term real interest rate is assumed to be 2% from 2050 on, and to converge to this value over a period of 30 years. This implies that the real interest rate will remain negative until 2035.

Expressing the ADL of the unfunded defined benefit schemes of government employees and social security schemes in terms of GDP provides an intuitive idea of their total size. With a long-term discount rate of 2%, the ADL/GDP ratio for 2018 is determined at 379%; using an alternative long-term discount rate of 3%, the ratio would be 342%. If the hypothesis about the evolution of the real interest rate is kept

constant at 3% throughout the entire period, as was the case for the first submission of Table 29, the ADL/GDP ratio is now slightly lower (258%) relative to 2015 (274%).

When interpreting the values of Table 29, one should keep in mind that the pensions entitlements are presented as accrued-to-date liabilities. Accrued-to-date liabilities do not represent public debt and are not an indicator of the financial sustainability of the pension systems and are only appropriate for national accounts purposes. An assessment of the budgetary consequences of population ageing, including those for the Belgian pension system, can be found in the reports of the AWG and the Belgian Study Committee on Ageing.

Synthèse

Le tableau supplémentaire 29 du programme de transmission d'Eurostat couvre les régimes de pensions légales et de pensions complémentaires de l'assurance sociale en Belgique. Il inclut les droits à la pension acquis des régimes de pension complémentaires (second pilier de pension) ainsi que les droits acquis (ou les engagements) à la pension légale du régime du secteur public et ceux du régime général de sécurité sociale en Belgique (premier pilier de pension), tous deux organisés par répartition. L'Institut des Comptes Nationaux est responsable de la transmission du tableau à Eurostat. Il a confié à la Banque Nationale de Belgique (BNB) et au Bureau fédéral du Plan (BFP) le soin de l'élaboration du tableau supplémentaire.

Le tableau 29, défini dans le Système européen des comptes (SEC 2010), est destiné à donner un aperçu complet et cohérent des droits à la pension constitués dans un pays et à permettre la comparabilité entre les pays. Il rassemble dès lors des informations déjà enregistrées dans les comptes nationaux principaux (soit les colonnes A à F du tableau 29) et des informations sur les régimes de pension par répartition, qui ne sont pas repris dans les comptes principaux (colonnes G et H du tableau 29). La contribution du BFP au tableau 29 consiste en la compilation des colonnes G et H. Ces colonnes reprennent les engagements de pension des régimes de pensions légales définis comme la valeur présente actualisée des pensions futures des bénéficiaires actuels ainsi que des bénéficiaires futurs qui ont déjà accumulé des droits au moment de l'évaluation. Les pensions considérées ici sont les pensions de retraite et les pensions de survie. Sont exclus les régimes d'assistance sociale (garantie de revenus aux personnes âgées et revenus d'intégration), les allocations d'invalidité, les allocations de chômage avec complément d'entreprise pour les non-demandeurs d'emploi ainsi que les pensions individuelles constituées à titre privé. Les engagements de pension des régimes de pensions complémentaires (second pilier) sont repris dans les autres colonnes du tableau 29.

Ce rapport commente les hypothèses sous-jacentes à la modélisation et la méthodologie d'estimation détaillée des droits à la pension acquis. Les valeurs présentées dans ce rapport seront envoyées à Eurostat dans le cadre de la transmission finale des tableaux. Les informations transmises comprendront le tableau 29, deux tableaux alternatifs calculés sur la base d'un taux d'actualisation différent et les fact sheets sur les régimes de pension comme requis par Eurostat. Ce rapport représente une mise à jour du « Grant Report » de la première soumission des données du tableau 29 publié en octobre 2017 (Brys, 2017).

La projection des droits à la pension acquis est très sensible à l'hypothèse sur le taux d'actualisation. Selon l'hypothèse formulée par le Working Group on Ageing Populations and Sustainability (AWG) du Comité de politique économique du Conseil de l'UE pour le rapport sur le vieillissement de 2021, le taux d'intérêt réel à long terme est supposé atteindre 2 % à partir de 2050, et converger vers cette valeur sur une période de 30 ans. Cela implique un taux d'intérêt réel négatif jusqu'en 2035.

Exprimer les droits à la pension acquis du régime du secteur public et du régime général de sécurité sociale en termes de PIB, donne une idée intuitive de leur ampleur. Avec un taux d'actualisation à long terme de 2 %, ils représentent 379 % du PIB. Avec un taux d'actualisation à long terme alternatif de 3 %, ils représentent 379 % du PIB.

le ratio est estimé à 342 %. Si l'hypothèse de l'évolution du taux d'intérêt réel est maintenue constante à 3 % tout au long de la période, comme dans le cas de la première soumission du tableau 29, le ratio obtenu des droits acquis sur le PIB est légèrement plus faible (258 %) que celui de 2015 (274%).

Pour interpréter les valeurs du tableau 29, il convient de garder en mémoire que les droits à la pension sont présentés comme un engagement existant à une date donnée. Les droits à la pension acquis à une date donnée ne représentent pas la dette publique et ne constituent pas un indicateur de la soutenabilité financière des systèmes de pension. Ils ne sont dès lors pertinents que pour la comptabilité nationale. L'AWG et le Comité belge d'étude sur le vieillissement évaluent les conséquences budgétaires du vieillissement, y inclus ceux relatifs au système de pension belge, dans leurs rapports respectifs.

Synthese

De aanvullende tabel 29 van het Eurostat transmissie programma heeft betrekking op de wettelijke en de aanvullende pensioenstelsels van de sociale verzekering in België. Deze omvat werkgerelateerde pensioenrechten buiten de overheid (2^{de} pijlerpensioenen), evenals de tot heden opgebouwde pensioenaanspraken op (c.q. verplichtingen inzake) overheidspensioenen en op pensioenen binnen de sociale zekerheid in België, die beide omslagstelsels zijn (1^{ste} pijlerpensioenen). Het Instituut voor de Nationale Rekeningen is verantwoordelijk voor de overdracht van deze tabel aan Eurostat. Het heeft de taak om deze aanvullende tabel op te stellen toevertrouwd aan de Nationale Bank van België en het Federaal Planbureau.

Tabel 29 wordt beschreven in ESA 2010, het European System of Accounts 2010 en heeft als doel een compleet en consistent beeld te geven van de pensioenverplichtingen in een bepaald land en de vergelijking tussen landen te bevorderen. Hiertoe combineert de tabel informatie die reeds in de standaard nationale rekeningen is opgenomen (kolommen A tot en met F van de tabel 29) en informatie over pensioenstelsels gebaseerd op omslagstelsel (wettelijke pensioenstelsels) die niet in deze standaard nationale rekeningen is opgenomen (kolommen G en H van de tabel). De bijdrage van het FPB aan Tabel 29 bestaat uit de opstelling van kolommen G en H. Deze kolommen omvatten gegevens over de huidige pensioenaanspraken (resp. pensioenverplichtingen) binnen de wettelijke pensioenen, dat wil zeggen de huidige contante waarde van de toekomstige pensioenen van huidige pensioentrekkingen en de pensioenaanspraken van toekomstige gepensioneerden, die op de referentiedatum al loopbaanjaren hebben opgebouwd. De pensioenen omvatten ouderdoms- en overlevingspensioenen. Het bijstandsstelsel (inkomensgarantie voor ouderen, leefloon), uitkeringen voor arbeidsongeschiktheid en werkloosheidsuitkeringen met bedrijfstoeslag zijn uitgesloten, evenals individuele pensioenverzekeringen. Aanspraken op arbeidsgerelateerde aanvullende pensioenen (2^e pijlerpensioenen) worden geregistreerd in andere kolommen van tabel 29.

Het rapport beschrijft de onderliggende assumpties van het model en de methodologie die gevolgd wordt bij het schatten van de verworven pensioenrechten. De bedragen die in dit rapport worden gepresenteerd zijn de waarden die in de transmissie naar Eurostat zullen worden verstuurd. De overgemaakte informatie zal bestaan uit de tabel 29, twee alternatieve tabellen met een verschillende verdisconteringsvoet en de fact sheets over de pensioenstelsels zoals gevraagd door Eurostat. Dit rapport vormt een actualisering van het Grant Report over de eerste transmissie van Tabel 29 in oktober 2017 (Brys, 2017).

De projectie van de verworven pensioenrechten is erg gevoelig voor de assumpties inzake de discontovoet. Volgens de hypothese door de Working Group on Ageing Populations and Sustainability (AWG) van het Comité voor de economische politiek van de Raad van de EU voor het Ageing Report van 2021, zou de langdurige reële interestvoet vanaf 2050 2% bedragen, en over een periode van 30 jaar naar deze waarde convergeren. Dit impliceert dat de reële rente negatief zou zijn tot 2035.

Door de verworven rechten op overheidspensioenen en op pensioenen binnen de sociale zekerheid uit te drukken ten opzichte van het bbp, krijgen we een intuïtief idee van de omvang van deze verworven

rechten. Bij een discontovoet van 2 % op lange termijn bedragen deze 379 % van het bbp; bij een alternatieve discontovoet van 3 % zou deze verhouding 342 % zijn. Bij constante hypothese inzake de evolutie van de reële interestvoet is deze verhouding licht gedaald ten opzichte van 2015. Onder de hypothese van een constante waarde van de reële interestvoet van 3 % gedurende de gehele periode, zoals het geval was in de eerste transmissie van Tabel 29, dan zou de verhouding tussen verworven rechten en bbp nu enigszins lager zijn (258 %) dan in 2015 (274 %).

Bij het interpreteren van de bedragen in tabel 29 moet men steeds in gedachten houden dat de pensioenverplichtingen gepresenteerd worden als tot nu verworven rechten. De verworven pensioenverplichtingen zijn niet op te vatten als schulden van de overheid en ze zijn geen indicator van de budgettaire of financiële houdbaarheid van de pensioenstelsels; ze zijn alleen geschikt om gebruikt te worden in de nationale rekeningen. De AWG en de Belgische Studiecommissie voor de Vergrijzing evalueren de budgettaire gevolgen van de vergrijzing, inclusief die voor de pensioenstelsels, in hun respectievelijke rapporten.

1. Introduction

The supplementary table 29 on pension schemes in social insurance is part of the European System of National and Regional Accounts 2010 (ESA 2010) Transmission Program and is published by Eurostat. The idea behind the table is to establish complete and consistent coverage of pension entitlements in a country and to promote comparability across countries. Therefore, it brings together information already shown in the standard national accounts (columns A to F of Table 29) and information on unfunded pension system (the statutory pension scheme), which are not reported in the standard national accounts (columns G and H of Table 29).

For Belgium, the National Accounts Institute is responsible for delivering this table to Eurostat. It has entrusted the National Bank of Belgium (NBB) and the Federal Planning Bureau (FPB) with the compilation of the supplementary table. The contribution of the FPB to Table 29 consists in compilation of columns G and H. Those columns include accrued-to-date pension entitlements/liabilities (ADL) in social insurance. ADL represent the present discounted value of accrued-to-date future pensions of current beneficiaries and future beneficiaries who already accumulated career years up to the valuation date. These entitlements do not represent public debt and are not an indicator of the financial sustainability of the pension system and are only appropriate for national accounts purposes. ADL should only be interpreted as an asset of the households in national accounts' terminology. In other words, "*ADL figures should be simply interpreted as the amount of resources that would have to be set aside today in order to finance all pension rights which have been earned up to a given year*" (Eurostat, 2020). This 'closed group' approach thus excludes all future pensions of people not yet born and future immigrants, as well as the pension rights of the current population that are to be accumulated after the valuation date. Pension rights are calculated according to the legislation that will be in force in each future year, if this legislation is already enacted now, i.e. passed in the appropriate legislature. An example of this is the raising of the statutory retirement age to 66 in 2025 and 67 in 2030. The analysis in this report is different from the sustainability analysis which relies on a more forward-looking approach, usually including all future flows of pension benefits (open group approach). An assessment of the budgetary consequences of population ageing, including those for the pension system, can be found in the reports of the Working Group on Ageing Populations and Sustainability (AWG) of the Economic Policy Committee (EPC) of the EU Council and the Belgian Study Committee on Ageing.

This report is in fact an update of the Grant Report on the first transmission of Table 29 data from Belgium, which was submitted to Eurostat in October 2017 (Brys, 2017). Rather than extensively referring to that earlier publication, we decided to copy substantial parts from it where appropriate, so that the current report can be read without going back to that earlier text.

The report is structured as follows. After the introduction, chapter 2 briefly presents the microsimulation model MIDAS used to estimate ADL. Chapter 3 discusses key assumptions required in the modelling of pension entitlements. The columns and rows of the supplementary table are described in chapter 4. The report concludes with a brief analysis of ADL expressed in terms of GDP, presented in chapter 5. The sensitivity analysis on the discount rate required by Eurostat is covered in the Annexe 1, while the fact sheets covering the pensions schemes in columns G and H are provided in Annexes 2 and 3 respectively.

2. Model and data

The computation of the entries for rows 1, 7 and 10 of columns G and H is done by means of the MIDAS model. MIDAS (an acronym standing for ‘Microsimulation for the Development of Adequacy and Sustainability’) is a dynamic population model with dynamic cross-sectional ageing. It is used by the Federal Planning Bureau in its adequacy assessment of pensions in Belgium.

MIDAS is a microsimulation model, meaning that it models on the level of individuals grouped in households rather than on aggregate data. It is also a dynamic population model with dynamic cross-sectional ageing. This means that it starts from a cross-sectional dataset representing a population of all ages at a certain point in time. The model then simulates the life spans of the individuals in the dataset, including household formation, labour market participation, earnings and other incomes, and retirement, over a specified number of future years. During their active years, the individuals build up pension rights, which result in a pension benefit when the individuals retire. See Dekkers et al. (2015) for more details.

In this context, MIDAS is aligned with projections and assumptions from the semi-aggregate MALTESE model in its version set up in the framework of the AWG of the EPC. This implies that the distributions of the population by age and by labour market position as well as assumptions about the wage growth rate are consistent with the AWG.

MIDAS uses a representative sample from the Belgian population in 2011 based on administrative data. The sample is extracted from the Datawarehouse Labour Market and Social Security of the Crossroads Bank for Social Security. It contains a little more than 600 000 individuals, with retrospective data that is complete for wage earners, but only partial for civil servants and self-employed workers (missing data are imputed). The dataset is supplemented with information from the 2011 population census and a dataset containing fiscal information.

Using these data and assumptions and following the PBO approach (see below), MIDAS calculates for every current pensioner, the expected amounts of retirement and survival benefits in each future year. For every current contributor, the model also projects future wages, as well as future pensions for the completed careers that will be corrected pro rata to the career accumulated up the valuation date. Projected wages include both actual and imputed wages for periods of unemployment, sickness or disability.

3. Assumptions

3.1. Base year

The supplementary table on pension schemes in social insurance is a mandatory table for all EU member states. It must be transmitted every three years, at base year plus 24 months. The first transmission was in 2017 and Table 29 was compiled with 2015 data. For the second (present) exercise, 2018 data must be transmitted by the end of 2020. Contributions, payments of benefits and transfers are those realised during the base year 2018. Changes in entitlements due to negotiated changes in scheme structures are included if they result from pension reforms enacted during 2018. The measures enacted after 2018 are excluded.

3.2. Types of benefits covered by the supplementary table

The focus of the supplementary table is on the old-age and early retirement pensions, as well as survivors' benefits. Therefore, the social assistance schemes (guaranteed income for elderly and guaranteed minimum income in social assistance), disability benefits² and unemployment benefits with company allowance for non-job seekers, as well as benefits from individual insurance policies are excluded. The concept of survivors' benefits usually includes widows' and orphans' benefits. However, orphans' benefits are not yet modelled in MIDAS and are hence not included in the supplementary table.

All pension entitlements reported in the table are expressed in gross (before tax and social contributions) terms.

3.3. Discount factor

The discount factor $\delta^{t,Y}$, used to calculate the present value in base year Y of a future benefit to be received in year t, is equal to

$$\delta^{t,Y} = \frac{1}{(1 + r_t)^{t-Y}} \quad (1)$$

where r_t represents the interest rate (discount rate) in year t. As recommended by Eurostat (2020), the interest rate is aligned with the one adopted by the AWG in the 2021 Ageing Report. The ultimate long-term real interest rate is assumed to be 2 % from 2050 on. National real interest rates are assumed to converge to the 2 % long-term value over a period of 30 years. For 2030 intermediate country-specific convergence targets have been set for nominal long-term interest rates (European Commission, 2020). For Belgium this is set at 1.17%, which corresponds to a real interest rate of -0.83%, given an expected inflation rate of 2.00%. For 2019 the observed interest rate is used. The resulting development of the real

² The old-age pensions of civil servants granted because of physical inability are included in the supplementary table along with the old-age pensions of civil servants. Civil servants can retire due to physical inability well before the early or statutory retirement age. In that case, their pension benefits are computed based on the career prior to the date of retirement and are not revised at the statutory age.

interest rate until 2070 is shown in Figure 1.³ Note that the real interest rate is expected to remain negative until 2035, which implies that for all previous years, the discounted value of entitlements is larger

than the original, not discounted one.

The projection of the ADL is very sensitive to the assumed discount rate. For this reason, sensitivity analyses have been carried out, in which the supplementary table is compiled with the long-term interest rates set at +1 and -1 percentage point, respectively, relative to the base scenario. As shown in Figure 1, until 2030 the real interest rate is the same in all scenarios, and between 2030 and 2050 it converges to the long-term values set for each scenario.

3.4. Inflation

Future flows (benefits and wages) are projected in constant prices and are thus expressed in real terms. Therefore, inflation expectations are not considered.

3.5. Wage growth

We follow the recommendations by the Eurostat (2020) and use the projected benefit obligations (PBO) approach to project future wages. According to this approach, all future incomes and their increases (general wage increase and/ or promotions) are taken into account in the pension computation. The present discounted value of future payments is then adjusted pro rata to the career accumulated up to 2018 (with respect to the career at the moment of person’s retirement).⁴ The PBO approach is regarded as a more prudent measure of what the eventual level of entitlement is likely to be (see section 2.2 and Box 4 of Eurostat (2020) for the arguments in favour of PBO). The PBO approach is applied to a closed group of individuals: only current pensioners and non-pensioners who have already contributed are considered. As recommended by Eurostat (2020), we use the latest AWG productivity projections assumptions, reflecting labour productivity growth, for the wage growth (see section 2).

³ For the years between 2020 and 2030, the projected nominal interest rate is calculated by linear interpolation between the observed value for 2020 and the assumed value for 2030, while the projected inflation rate is calculated by linear interpolation between the currently observed value and the assumed long-term inflation rate, which is 2% from 2025 on. The projected real interest rate is the difference between these two. Between 2030 and 2050, the real interest is assumed to converge linearly to the long-term value of 2%.

⁴ The second possible approach mentioned by Eurostat (2020) is accumulated benefit obligations (ABO). This approach only considers the present value of benefits earned to date. Thus, there are no projected wages and future benefits are computed only based on the career accrued to date. Eurostat recommends PBO approach as it is more suited for the exercise.

3.6. Demographic assumptions

Following Eurostat (2020) recommendations, we use the Eurostat's latest available population projections relying on the demographic assumptions of mortality, fertility and migration in the modelling of the pension scheme.

3.7. Indexation and living standards adjustment of pension benefits

In Belgium, pensions are adjusted to living standards in real terms. Each year, as stipulated in the Generation Pact of 2005, a total budget for the adjustment of social benefits to living standards is determined following certain parameters. The precise allocation of this budget is a political decision, which varies each year. As future government measures remain unknown, we use for the pension projections the parameters used in the calculation of the budget. We assume an annual growth of 1.25% for wage ceilings and the minimum claim, 1% for lump-sum benefits, 0.5% for non-lump-sum benefits in the wage earners' and self-employed schemes. The civil servants' projected pensions are assumed to grow at the same pace as the real wages of working civil servants (1.5%, which is the productivity growth in the long run) less 0.4% (average historical difference between the wage growth rate and the welfare adaptation of civil servants' pension). This corresponds, in the long term, to an annual growth rate of 1.1%.

3.8. Minimum income provisions in pension schemes

In all pension schemes (wage earners, self-employed and civil servants), a minimum pension is guaranteed. Additionally, the wage earners' scheme has a system of minimum claims per working year. The minimum pension is granted pro rata of the completed career relative to the full career. Both kinds of minimum income provisions can only be accessed when a certain career duration can be proved (e.g. 2/3rd of a full career for the minimum pension in the wage-earner scheme). Following the PBO approach, the career of each person is projected up to the pensionable age. When computing the accrued rights pro rata of the career up to 2018, the minimum rights will also be accounted for pro rata of the career up to 2018.

3.9. Labour force participation and retirement rates

Labour force participation rates, as well as rates of disability and other types of inactivity, are derived from macro-economic projections produced in the framework of the AWG and broken down by age group and gender. People leaving the labour force who are eligible for early retirement, or when they reach the statutory retirement age, are assumed to retire.

4. Columns G and H of the supplementary table

Columns G and H of the supplementary table represent pension entitlements of pension schemes that are not recorded in the core national accounts, although a part of their transactions does appear in it. Column G covers government schemes for its own employees. This means that this column includes information on the first pillar pension benefits of civil servants. Column H covers the social security pension schemes, i.e. the first pillar pension scheme for wage earners and self-employed. Some specific pension schemes for civil servants were originally set up by general government or regional authorities, but as today do no longer depend on general budget for their financing (public agencies with a semi-autonomous character, the police force and pension fund structures for local authorities, ...). Coherent with current practices in the national accounts, these pension schemes are reported under the social security schemes, column H.

As mentioned in sub-section 3.2, pension benefits in the supplementary table refer to old-age pension benefits and survivors' pension benefits. The fully compiled columns G and H of the supplementary table for 2018 are presented in Annexe 1.

This section describes in detail the compilation of the rows for columns G and H.

4.1. Row 1 - Pension entitlements, opening balance sheet

Row 1 for both columns G and H is compiled using the accrued-to-date liabilities (ADL) simulated by microsimulation model MIDAS described in section 2. It represents the situation on 1st January 2018. Any policy reforms enacted during 2018, should not be included in this row. The effects of such reforms on the ADL should be reported in row 7.

As mentioned in sub-section 3.5, we use the PBO approach applied to the closed group of individuals (only current pensioners and non-pensioners with already accrued rights are considered) along with the pro rata method. The pro rata method allows to correct the present value of all future pension payments of current non-pensioners so that only the portion of benefits that has been accrued up to the valuation date (here the start of the base year 2018) is considered. This means that future pension benefits are computed using both accrued and future rights and then corrected by applying a pro rata basis factor. The latter is equal to the number of contributory years accumulated up to the valuation date (actual contributory period) divided by the number of contributory years at the moment of retirement (i.e. actual contributory period plus projected future contributory period).

Column G

Column G includes ADL of civil servants. As described earlier, a part of these ADL represents the actual value of the pension entitlements of civil servants whose pension scheme was once set up by general government or regional authorities, but as today do not longer depend on general budget for their financing (public agencies with a semi-autonomous character, the pension fund structures for local authorities, ...). The part of the ADL that belongs to these categories is estimated pro rata by means of the

benefit payments that are reported in the national accounts. Based on this information, 27.5% of the computed ADL for civil servants are reported under column H as social security entitlements. The remaining 72.5%, which represent 315,621 million euro, are reported in column G.

Column H

Column H includes ADL for wage earners and self-employed, increased with the part of civil servants' ADL whose pension scheme does no longer depend on federal budget. This represents a total of 1,428,167.8 million euro.

4.2. Row 2 - Increases in pension entitlements due to social contributions

Row 2 includes employer's and household social security contributions, less the pension schemes service charges if these are deducted from the pension entitlements. It is given by

$$\text{Row 2} = R\ 2.1 + R\ 2.2 + R\ 2.3 + R\ 2.4 - R\ 2.5 \quad (2)$$

Rows 2.1 to 2.5 are explained below.

4.2.1. Row 2.1 - Employer actual social contributions

This row records the actual social contributions paid by employers.

Column G

In principle, there are no actual social contributions made by the government for its own employees. Public agencies and public enterprises that must pay a contribution to the general government to finance the pensions of their statutory personnel are reported under the social security schemes of column H. Row 2.1 of column G is filled in with 0.

Column H

The data on total employer's social contributions in social security schemes is reported in the national accounts. However, only part of these contributions is used to finance first pillar pensions. The remaining part goes to the other protection schemes (sickness and disability, unemployment, occupational illnesses, profession-linked accidents, birth and family allowances⁵ and special social security scheme for seafarers). There is a global contribution rate for all protection schemes and no specific rate by scheme.

To identify the part of contributions allocated to the pension schemes, we proceed in two steps. First, the amount of employer's contributions paid for civil servants is separated from the amount paid for wage earners. Contributions for civil servants are collected on behalf of workers whose pension scheme does no longer depend on the federal budget. Those contributions are used in their entirety to finance

⁵ Since the 6th State Reform (enacted in 2012), family allowances are no longer financed by the global management (characterised by a single institution collecting and distributing social contributions) but are the responsibility of communities and regions.

civil servants' pensions. In a second step, we estimate the part of contributions on behalf of wage earners that is used to finance public pensions.

The part of contributions paid for civil servants is obtained using the detailed national accounts.⁶ 100 percent of these contributions are allocated to the pension scheme. The part of contributions for wage earners allocated to pensions is estimated using historical contribution rates. Since the introduction of the global management of the NSSO (National Social Security Office) in 1995, the contributions are no longer distributed between the protection schemes according to the separate contribution rates but based on their cash flow needs. By lack of information on the amount of these transfers to the pension schemes, we use historical breakdown by type of protection schemes that existed before 1995. The historical employer's contribution rate for pensions schemes was 8.86%. It is applied to the current global contribution rate to obtain the percentage of total contributions related to pensions.

The current global employer's contribution rate depends on the worker's category (white- or blue-collar working in a private or public sector). As there is no information on the proportion of each category, all workers are assumed to be white-collar working in the private sector. Neither the slightly different social security contributions of white-collar workers in the public sector nor the 108% rate applied to the gross salary of blue-collar workers have been considered. This might have a minor impact on the estimates.

In 2018, the global employer's contribution rate in the private sector for a white-collar worker was 25.40%.⁷ Applying the historical contribution rate for pensions schemes to this global rate, we obtain 34.88%. Thus, we estimate that 34.88% of total employer's contributions reported in national accounts in 2018 (reduced by employer's contributions paid in civil servants' scheme) are related to pensions.

The final amount reported in row 2.1 (14,497.2 million euro) represents the sum of the employer's contributions paid for civil servants (collected in a pension system that no longer depends on the budget of the federal authorities) and the estimated part of the employer's social security contributions allocated to pensions schemes.

4.2.2. Row 2.2 - Employer imputed social contributions

Employer imputed social contributions for defined benefit scheme usually represent the balancing item, including all changes in pension benefits over the base year that are not covered by the other rows of the supplementary table. This includes 'experience effects' "*where the observed outcome of pension modeling assumptions (real wage growth rate, discount rate, etc.) differs from the levels assumed*".⁸

This sentence refers in a rather oblique way to the fact that, given the unfunded nature of the social insurance pensions schemes, and due to wage and income ceilings, minimum pension provisions and other pension regulations, future pension rights correspond only weakly to current contributions. Also, social security contribution rates are not set with a view to cover future pension expenditures (and there

⁶ Personal communication, Modart C., National Bank of Belgium, 4 November 2020.

⁷ Source: https://www.vbo-feb.be/en/business-issues/social-security/cotisations-de-securite-sociale2/cotisations-sociales---premier-trimestre-2018_2018-01-08/, last consulted on 14 Augustus 2020.

⁸ Eurostat (2020).

are no specific pension contributions). This implies that the sum of the opening balance and the identifiable contributions, minus paid benefits (and minus some minor items) is not necessarily equal to the closing balance. The entry in row 2.2 (for column G; and the corresponding entry in row 3 for column H), reflecting ‘experience effect’, makes sure that the amounts balance out in the appropriate way. It can be interpreted as the residual of the other rows in Table 29.

Column G

Given that Belgian public pension system is defined benefit, general government imputed social contributions represent the balancing item for Column G. Therefore, as a balancing item, row 2.2 is computed after all the other rows have been compiled. It is given by

$$\text{Row 2.2} = R 10 - R 1 - R 2.1 - R 2.3 - R 2.4 + R 2.5 + R 4 - R 6 - R 7 - R 8 - R 9 \quad (3)$$

Row 2.2 is estimated to 6,947.3 million euro.

Column H

For social security schemes, row 2.2 is shaded black. Any ‘experience effects’ are recorded in row 3 and there are no entries in row 2.2.

4.2.3. Row 2.3 - Household actual social contributions

This row records the household actual social contributions.

Column G

In principle, civil servants do not pay social contributions to the public sector pension scheme. The contributions paid by civil servants whose pension system does no longer depend on federal or regional budgets (including the mandatory contributions for survivors’ pensions – widow's and orphan's fund) are reported under the social security schemes, Column H. Therefore, row 2.3 of column G is filled in with 0.

Column H

As stated in Eurostat (2020), the actual social contributions paid by households are published in the national accounts. Since the introduction of overall financial management in the Belgian social security system in 1995, separate contributions no longer exist for each of the social risks. Therefore, what is found in the national accounts is the total amount of social contributions. Only part of these contributions is aimed at financing first pillar pensions. The other part covers sickness and invalidity, professional illnesses, profession-linked accidents, etc.

The ‘households’ actual social contributions’ of the national accounts is subdivided in three socio-economic categories: wage earners (including active civil servants), self-employed and non employed persons (including retired civil servants paying contributions to widow's and orphan's fund). For each of the three socio-economic categories in the national accounts, the pension contributions must be

estimated based on the reported total social contributions. The estimates are done separately as the contribution rates in Belgium depend on the worker's socio-economic category.

To estimate the wage earners' social contributions, like in the case of employer's contributions, we must first deduce contributions made by active civil servants. All active civil servants contribute to the widow's and orphan's fund and those in a pension system that does no longer depend on the budget of the federal authorities, also contribute to first pillar pensions. Civil servants' contributions represent 1,719.3 million euro⁹ and are destined in their entirety to the pension scheme. The remaining amount of wage earners' contributions should be split between the public pension scheme and other protection schemes. The proportion used to finance public pensions is determined based on the historical rate applied before the global management. Before 1995, the household contribution rate for pensions was 7.5%. In 2018, the global contribution rate for households was 13.07%. Therefore, we estimate that 57.38% of the total contributions reported in national accounts (less civil servants' part) goes to pensions schemes. This part represents 9,586.5 million euro.

Like those of wage earners, self-employed total contributions are reported in national accounts, but under the global management an unknown part of them is related to pensions. Based on the historical rate before 1995, we assume that 55.629% of these total contributions is used to finance pensions schemes.¹⁰ The amount of household contributions paid by self-employed is estimated to 2,357.6 million euro.

The 'non employed persons' category covers several inactive states: pensioners (including those in civil servants' scheme paying contributions to widow's and orphan's fund), unemployed, etc. From those we must deduce the part that is paid by pensioners in the civil servants' scheme. This part represents 59.9 million euro and is used entirely to finance pensions. The remaining amount of non employed persons' contributions is split between pension schemes and other protection schemes. As there is no further information on the weight of each of the different inactive states, the pension contributions are estimated very roughly by using the proportion of pension contributions to the total social security contributions from wage earners. This proportion (57.38%) is applied on the social security contributions (less the part paid by pensioners in the civil servants' scheme), resulting in an estimated amount of 1,078.5 million euro paid to finance the social security pensions schemes.

The aggregate amount of the households' pension contributions paid by the three socio-economic categories (wage earners, self-employed and non employed persons) adds up to a total of 14,801.9 million euro.

4.2.4. Row 2.4 - Household social contribution supplements

Row 2.4 captures the property income earned or imputed in the scheme. In case of defined benefit pension schemes, the property income is equivalent to the interest rate (-0.74% in 2018¹¹) times the pension entitlements at the opening of the balance sheet (i.e. pension entitlements from row 1):

⁹ Personal communication, Modart C., National Bank of Belgium, 4 November 2020.

¹⁰ SPF Sécurité sociale (2014).

¹¹ Based on the nominal interest rate of 0.79% (source: AMECO, PVGD) and inflation rate of 1.53% (source: Eurostat, TEC00097) observed in 2018.

$$\text{Row 2.4} = (1 + \delta) \times R 1 \quad (4)$$

The property income is estimated to -2,347 and -10,619.9 million euro for columns G and H respectively.

4.2.5. Row 2.5 - Pension scheme service charges

Row 2.5 covers the cost of running the pensions schemes. These costs consist of wages and social contributions, but also of normal operating costs such as overheads, rents for buildings and investment in furniture and ICT equipment. Federal Pensions Service (FPS), responsible for the payment of pensions, is a public service with the costs of running the pensions schemes financed by the overall budget of the federal state. No costs are charged to the pensions schemes members: they are not deducted from the social contributions, nor are they a charge on the pension entitlements. For this reason, row 2.5 is filled in with 0 for both columns.

4.3. Row 3 - Other (actuarial) change of pension entitlements in social security pension schemes

Row 3 includes other (actuarial) change of pension entitlements in social security pension schemes. More precisely, it represents cases “where actual social contributions to the social security pension scheme are not actuarially based”¹² and thus, reflect an imputed contribution of this scheme (outside of the employer’s responsibility). In other words, row 3 represents the difference between the discount rate and the internal rate of return of the scheme (i.e. “the discount rate that equalises the actual contributions paid and the discounted value of pension entitlements accrued through those contributions”)¹³. row 3 also includes any ‘experience effects’ that were already mentioned in sub-section 4.2.2 for row 2.2. As explained there, this row can be regarded as a residual entry in the compilation of column H of Table 29.

Column G

This row is irrelevant to defined benefits schemes for general government employees. Any ‘experience effects’, where the obtained results of pension modelling assumptions (real wage growth rate, discount rate, etc.) differ from the levels assumed, are covered by row 2.2.

Column H

In practice, for column H, this row represents the balancing item for social security schemes and as such, is computed after all the other rows have been compiled. The computation equation is similar to row 2.2 for Column G:

$$\text{Row 3} = R 10 - R 1 - R 2.1 - R 2.3 - R 2.4 + R 2.5 + R 4 - R 6 - R 7 - R 8 - R 9 \quad (5)$$

The row is estimated for 2018 to 20,143.6 million euro.

¹² Eurostat (2020).

¹³ Eurostat (2020).

4.4. Row 4 - Reduction in pension entitlements due to payment of pension benefit

Row 4 contains information on the amount of pension benefits distributed during the base year. This means that row 4 settles some of the pension entitlements reported at the opening of the balance sheet (row 1). The information on pension benefits paid in 2018 can be found in the national accounts. This information is supplemented with the data on civil servants provided by the Federal Pensions Service (FPS).¹⁴

Column G

A total amount of 12,216.5 million euro was spent in 2018 on old-age and survivors' pensions in the public sector scheme. This amount does not include the benefit payments to the civil servants whose pension scheme does no longer rely on the budget of the general government for its financing. Those benefit payments are reported in column H.

Column H

A total amount of 35,269 million euro was spent in 2018 on old-age and survivor's pensions in the social security schemes, including pensions paid to civil servants whose pension scheme does no longer rely on the budget of the general government for its financing.

4.5. Row 5 - Changes in pension entitlements due to social contributions and pension benefits

Row 5 represents the balance of changes in pension entitlements due to social contributions (+) and pension benefits (-). In practice, it is computed as follows

$$\text{Row 5} = R 2 + R 3 - R 4 \quad (6)$$

Row 5 is estimated at -7,616.2 and 3,553.8 million euro for columns G and H respectively.

4.6. Row 6 - Transfers of pension entitlements between schemes

Most of the data on transfers of pension entitlements between schemes (from and into civil servants' and wage earners' schemes) comes from the Federal Pensions Service (FPS).¹⁵ The remaining statistics (on transfers from and into the self-employed scheme) are published by the National Institute for the Social Security of the Self-employed (NISSE).¹⁶

Column G

The detailed categories of transfers from and into civil servants' scheme are illustrated in Table 1.

¹⁴ Personal communication, Weerts J., Federal Pensions Service, 8 May 2020.

¹⁵ Personal communication, Weerts J., Federal Pensions Service, 8 May 2020.

¹⁶ <https://inastirapportannuel.be/2018/gestion-financiere-globale/>, last consulted on 14 Augustus 2020.

Table 1 Pension entitlements transferred from and into the civil servants' scheme (column G)

| From the civil servants' scheme into | | Into the civil servants' scheme from | |
|--|----|--|----|
| The wage earners social security scheme | | The wage earners social security scheme | |
| The self-employed social security scheme | NA | The self-employed social security scheme | NA |
| European pension schemes | | European pension schemes | NA |

Note: NA stands for Not Applicable

The transfers of pension entitlements from the civil servants' scheme into the wage earners' scheme can arise in two cases: when the person's career as civil servant is too short to give right to pension benefits in the civil servants' scheme or when the person is dismissed as a result of a disciplinary sanction. In both cases the career years as civil servant will be recognised in the social security scheme and constitute rights for a wage earners' pension. This results in a transfer of pension entitlements from civil servants' scheme to wage earners' scheme.

It is possible for a non-statutorily appointed (= contractual) employee or a temporarily appointed civil servant to become a statutorily appointed civil servant. Under certain conditions, their past career as wage-earners can be taken into account for the computation of the civil servants' pension.¹⁷ In this case, the pension rights are transferred from the social security scheme of wage earners towards the pension scheme of civil servants.

Another situation where pension rights can be transferred from the civil servants' pension scheme is when the person starts working for the European Community and his pension rights are recognised.

For the year 2018, the balance of these transfers from and into the civil servants' pension scheme is 260.3 million euro.

Column H

The possible transfers from and into the social security schemes are summarised in Table 2.

Table 2 Pension entitlements transferred from and into the social security schemes (column H)

| From the social security scheme of | | Into the social security scheme of | |
|--------------------------------------|----|--------------------------------------|----|
| wage earners into | | wage earners from | |
| The pension scheme of civil servants | | The pension scheme of civil servants | |
| European pension schemes | | European pension schemes | NA |
| self-employed into | | self-employed from | |
| The pension scheme of civil servants | NA | The pension scheme of civil servants | NA |
| European pension schemes | | European pension schemes | NA |

Note: NA stands for Not Applicable

As mentioned for column G, in some cases past career as wage earner can be transformed in working years in civil servants' scheme (contractual wage earner in the public service becoming statutory civil servant). In this case, the pension rights are transferred from the social security scheme towards the pension scheme of the civil servants. A similar transferring mechanism does not exist for the self-employed. Another situation in which pension rights can be transferred from the social security schemes (both wage earners and self-employed) is when a person starts working for the European Community and their pension rights are recognised.

¹⁷ Janvier, R., Janssens, J. (2014)

We already mentioned (column G) that there is a flow of pension entitlements from civil servants' scheme into wage earners' scheme. These transfers thus appear in both columns G and H. For the year 2018, the final outcome of transfers from and into the social security schemes is estimated to -264.3 million euro.

4.7. Row 7 - Change in entitlements due to negotiated¹⁸ changes in scheme structure

Row 7 reports changes in pension entitlements that are due to the negotiated reforms affecting persons' past service (= benefits accrued in past years). The reforms should be formally enacted during the base year (2018) and must be voted by the parliament. If formally enacted reforms have no impact on current pension entitlements, no estimate or amount should be recorded. Only reforms affecting the accrued-to-date rights of the existing pensions schemes' members are to be reported.

In practice, row 7 represents the difference in ADL at the closing of the balance sheet between the results of simulations including reforms enacted during 2018 (row 10) and the results of simulations without those reforms.

In 2018, a reform of the pension system has been enacted. It concerns the cancellation of the above-mentioned rule on the transfer of pension rights from the wage-earner scheme to the civil servant scheme. Under certain conditions, past career years of contractual wage-earners in the public service can be considered as years of services as civil servant when they become statutory civil servant. This cancellation concerns appointments as civil servants from the 1st December 2017 and does not apply to the education sector. As MIDAS does not model this transfer rule, it is not possible to estimate the impact of this reform. Therefore, row 7 is left blank.

Furthermore, it is worth to be noted that this modelling issue does not impact values reported in row 6. Indeed, those values come from statistics and not from modelling.

4.8. Row 8 - Changes in entitlements due to revaluations

Row 8 records changes in key model assumptions (discount rate, wage growth rate and inflation rate) affecting pension entitlements in the actuarial computations. These changes represent the difference between the opening of the current and closing of the previous year's balance sheets, all other assumptions (e.g. demographic) being kept unchanged. For this exercise, row 8 should represent the difference between the opening sheet in 2018 and the closing sheet in 2017. However, the last exercise was done for 2015, making the compilation of row 8 impossible with the currently available data. The row is left blank.

¹⁸ Changes in pension entitlements under social security schemes approved by the parliament authorities are recorded as if the changes had been negotiated (Eurostat (2020)). The pension scheme for civil servants is in fact not a social security scheme. Even so, the impact of the pension reforms affecting civil servants should also be reported in row 7.

4.9. Row 9 - Changes in entitlements due to other changes in volume

Other changes in volume due to changes of non-key assumptions in the actuarial computations, such as changes in the demographic assumptions, are reported here. Like for row 8, these changes represent the difference between the opening of the current and closing of the previous year's balance sheets, all other assumptions (e.g. related to revaluations) being kept unchanged. The data on the supplementary table for the base year 2017 being unavailable, row 9 is left blank.

4.10. Row 10 - Pension entitlements, closing balance sheet

Row 10 represents ADL at the closing of the balance sheet (i.e. 31 December 2018). The compilation is done in the same way as for row 1 described in sub-section 4.1, but one year later and with simulations including the effects (if any) of the policy reforms enacted during 2018.

This row should be interpreted as the result of the rows of the column: the present value of pension entitlements at the beginning of the reporting period, increased by social contributions and financial return on the assets, decreased by pension settlements and if necessary corrected for model corrections or changes in assumptions:

$$\text{Row 10} = R 1 + R 5 + R 5 + R 7 + R 8 + R 9 \quad (7)$$

Recall, though, that in the actual calculations the amounts in row 10 are provided by the model used to project pension entitlements. As explained above, the residual rows 2.2 (in column G) and 3 (in column H) are used to ensure that equation (7) is met.

At the closing of the balance sheet, the pension entitlements are estimated to 308,265.1 and 1,431,457.3 million euro for columns G and H respectively.

5. ADL in terms of GDP

ADL measure the amount of money required by the pension system to meet its commitments in the theoretical case of closing down the system. Such a scenario is in theory ruled out for public or government-sponsored unfunded pension schemes. Expressing the ADL of the unfunded defined benefit schemes of government employees and social security schemes in terms of GDP gives an indication of the number of years a country would have to use its GDP to meet its pension commitments if it was to dedicate the entire GDP to it. It provides an intuitive idea of the total size of the ADL.

Table 3 ADL in terms of GDP in 2018
Million euro and percentages

| | Sensitivity 1: -1% | Base scenario | Sensitivity 2: +1% |
|----------|--------------------|---------------|--------------------|
| ADL | 1,970,526.2 | 1,739,722.4 | 1,572,313.7 |
| GDP 2018 | 459,531.6 | 459,531.6 | 459,531.6 |
| ADL/GDP | 429% | 379% | 342% |

With a long-term discount rate of 2%, the MIDAS model and its dataset, the assumptions made and the estimation procedures described in this report, the ADL/GDP ratio for 2018 is determined at 379%. The present value of the ADL of all first pillar pensions schemes in Belgium equals roughly 3 years and 10 months of the total Belgian production capacity in 2018. To illustrate the sensitivity of this ratio to the discount rate, two alternative ratios are computed, at a long-term rate of 1% and 3%, respectively leading to a ratio of 429% and 342%. The complete supplementary tables of the alternative scenarios can be found in annexe 1.

It is worth noting that Table 29 shows the pensions entitlements on an accrued-to-date basis. These are present values of the pension entitlements of the retired population and the part of pension entitlements that is already accrued by the future beneficiaries. As such, accrued-to-date liabilities do not represent public debt and are not an indicator of the financial sustainability of the pension system and are only appropriate for national accounts purposes. Accrued-to-date liabilities should only be interpreted as an asset of households in national accounts' terminology. An assessment of the budgetary consequences of population ageing, including those for the Belgian pension system, can be found in the reports of the AWG or the Study Committee on Ageing.

In the previous, first, submission of the Table 29 data (Brys, 2017), the ADL/GDP ratio in the base scenario in 2015 was estimated to 274%, which is 105 percentage points lower than in 2018. At first glance, the difference appears sizeable. However, these figures were estimated with different interest rates. In the previous exercise, the base scenario was estimated with a fixed real interest rate of 3%, while in the present exercise the assumed real interest rate in the base scenario is 2% in the long-term, with a long convergence period of 30 years; until 2034 real interests rate remain negative. To have a more valid comparison between the two exercises, we should keep the interest rate constant. When the real interest rate is fixed at a constant value of 3%, but with otherwise the same assumptions as for the base scenario, the ADL/GDP in 2018 turns out to be 258%, i.e. 16 percentage points lower than in 2015. There can be a number of reasons for this relatively small decline, including pension reforms and changes in the demographic and economic assumptions, e.g. about life expectancy and wage growth. It should be kept

in mind, though, that even at the same discount rate, without reforms and with unchanged modelling assumptions, the ADL would still change over time as pensions are paid out, while other people, including new entrants to the labour market, build up pension rights. Quantifying these various factors would require repeating the whole exercise for the intermediate years 2016 and 2017, which would go far beyond the limits of this report.

Annexe 2: Pension fact sheet - column G

1. General description of the scheme and the computation model

a. Coverage of the scheme

Column G covers the civil servants' pension scheme relying on the budget of the federal government. This scheme consists of the old-age pension (including old-age pensions of civil servants granted because of physical inability) and the survivor's pension. The pension expenditures for this scheme amount to 25.7% of total first pillar pension expenditures reported in national accounts for 2018.

Column G does not include the ADL of civil servants whose pension scheme does no longer depend on the budget of the federal government. These values are reported under the social security schemes, column H.

b. Institutional set-up

Data source

The microsimulation model estimating accrued-to-date pension entitlements uses administrative data for 2011 provided by the Datawarehouse Labour Market and Social Protection of the Crossroads Bank for Social Security. It includes over 600,000 representative individuals, with retrospective data that is complete for wage earners though only partial for civil servants and self-employed workers. The dataset is supplemented with information from the 2011 population census and fiscal information.

Institution managing the calculations

The institution responsible for Table 29 is the National Accounts Institute of Belgium. It has entrusted the National Bank of Belgium and the Federal Planning Bureau with the compilation of the supplementary table. Columns G and H are a responsibility of the Federal Planning Bureau.

c. Major formulas: benefit formula; indexation of benefits

Benefit formula

The retirement pension is calculated on the average wage of the last ten years of work (five years for people born before 1962) and is proportional to the career length, with the considered service years in the numerator and a *tantième* of 60 in the denominator. Some civil servants have a preferential denominator (55 in teaching and 48 years for magistrates and in academic services).

Civil servants can be granted a minimum pension, which is a fixed amount, provided they have 20 years of service. The pension benefit is also subject to a relative maximum of 75% of the reference wage and pensions are capped to an absolute maximum pension, which is a fixed amount.

Indexation of benefits

Civil servants' pensions are automatically adjusted to the health consumption price index and to the real wage increases of the active civil servants (the *péréquation*).

d. Type and structure of the computation model

MIDAS is a microsimulation model, meaning that the modelling is done on the level of individuals clustered in households rather than on aggregate data. It is also a dynamic population model with dynamic cross-sectional ageing. This means that it is based on a cross-sectional dataset representing a population of all ages at a certain point in time.

2. Assumptions and methodologies applieda. Discount rate

After 2050, an interest rate of 2% in real terms is used. Real interest rates are assumed to slowly converge to that value, starting from an observed value of -1.43% in 2019. For 2030 an intermediate country-specific convergence target has been set for nominal long-term interest rates of 1.17%, which for Belgium corresponds to a real interest rate of -0.83%, given an expected inflation rate of 2.00%.

b. Wage growth

Future wage growth is modelled at a rate of 1.5% in long term (from 2037 on).

c. Valuation method: ABO/PBO

PBO

3. Data used to run the modela. Mortality tables

MIDAS uses EUROPOP2019 data in the projections for Table 29.

b. Entitlement statistics; other relevant statistics

The entitlement statistics for 2018 are taken from the national accounts (government accounts) and Federal Pensions Service. Other statistics, such as on social contributions and transfers between schemes, come from the national accounts, Federal Pensions Service and National Institute for the Social Security of the Self-employed.

4. Reforms incorporated in the model

None.

5. Specific assumptions

a. How are careers modelled?

Future career evolution is projected by the microsimulation model MIDAS, using the projection of the aggregate numbers of civil servants by age and gender provided by the meso-economic model MALTESE (in its version set up in the framework of the Working Group on Ageing Populations and Sustainability), as well as behavioural equations for transitions between states.

b. How are survivors' pensions calculated?

Deaths are simulated through MIDAS' demographic module. If an (ex-)civil servant dies, the surviving partner becomes eligible for a survivor's pension. If the surviving partner has reached a minimum age, she/he will receive the survivors' pension. If she/he is younger than this minimum age, she/he will not receive a survivor's pension but a transitional benefit. The age condition was 46.5 in 2018 and will gradually increase to 50 by 2025.

A divorced spouse can also be entitled to a survivor's pension under certain conditions. The minimum age condition plays a similar role in these situations. This age condition was also 46.5 in 2018 and will gradually increase to 50 in 2025.

c. How is the retirement age modelled over time?

The statutory retirement age in Belgium is currently 65 (both men and women and all pension schemes). It will increase from 65 to 66 by 2025 and to 67 by 2030.

6. Any other comments

It is possible for a civil servant to start working for a European institution and to have his pension rights accrued in the Belgian pension scheme recognised by the European institution or its pension fund. The corresponding amount of contributions will then be transferred from the Belgian pension scheme towards the European pension scheme. These transfers explain why row 6 does not balance for the total economy.

Annexe 3: Pension fact sheet - column H

1. General description of the scheme and the calculation model

a. Coverage of the scheme

Column H covers the social security pension schemes for both wage earners and the self-employed. Both pension schemes consist of old-age pensions and survivors' pensions. The column also includes pension entitlements of the civil servants whose pension scheme does no longer depend on the budget of the federal government.

Of the total pension expenditures on first pillar pensions reported in the national accounts for 2018, 66.3% are allocated to the scheme for wage earners and 8% to the scheme for self-employed.

b. Institutional set-up

Data source

The microsimulation model estimating accrued-to-date pension entitlements uses administrative data for 2011 provided by the Datawarehouse Labour Market and Social Protection of the Crossroads Bank for Social Security. It includes over 600 000 representative individuals, with retrospective data that is complete for wage earners though only partial for civil servants and self-employed workers. The dataset is supplemented with information from the 2011 population census and fiscal information.

Institution managing the calculations

The institution responsible for Table 29 is the National Accounts Institute of Belgium. It has entrusted the National Bank of Belgium and the Federal Planning Bureau with the compilation of the supplementary table. Columns G and H are a responsibility of the Federal Planning Bureau.

c. Major formulas: benefit formula; indexation of benefits

Benefit formula

- Wage earners

The pension of wage earners is computed at 75% of the reference wage for the head of household with a dependent spouse and 60% in all other cases. The reference wage is calculated on the real or assimilated wages earned during the career up to a wage ceiling. These wages are adjusted to current prices. The sum of those adjusted wages over the career is multiplied by 1/45 (a full career is 45 years).

A guaranteed minimum pension exists for the pensions accrued over a career which equals at least two thirds of a full career in the wage earners' scheme. A minimum right per working year also exists if some conditions are met. There is no explicit maximum pension amount, though the wage ceiling mentioned above imposes an implicit maximum.

- Self-employed

The pension of self-employed individuals is computed at 75% of the reference wage for the head of household with a dependent spouse and 60% in all other cases. The working years before 1984 are valued at a fixed income, while for the working years as from 1984 the pension rights are based on the business income used to compute social security contributions and income tax, up to an income ceiling. The income is adjusted to current prices.

A minimum pension can be granted when the person can prove at least two thirds of a full career as a self-employed individual and/or wage earner. There is no explicit maximum pension amount, though the income ceiling mentioned above imposes an implicit maximum.

Indexation of benefits

Pension benefits are automatically adjusted to the health consumption price index and partially adjusted to living standards according to the 'Generation Pact'.

- d. Type and structure of the calculation model

MIDAS is a microsimulation model, meaning that the modelling is done on the level of individuals clustered in households rather than on aggregate data. It is also a dynamic population model with dynamic cross-sectional ageing. This means that it is based on a cross-sectional dataset representing a population of all ages at a certain point in time.

2. Assumptions and methodologies applied

- a. Discount rate

After 2050, an interest rate of 2% in real terms is used. Real interest rates are assumed to slowly converge to that value, starting from an observed value of -1.43% in 2019. For 2030 an intermediate country-specific convergence target has been set for nominal long-term interest rates of 1.17%, which for Belgium corresponds to a real interest rate of -0.83%, given an expected inflation rate of 2.00%.

- b. Wage growth

Future wage growth is modelled for wage earners and self-employed at a rate of 1.5% in long term (from 2037 on).

- c. Valuation method: ABO/PBO

PBO

3. Data used to run the model

- a. Mortality tables

MIDAS uses EUROPOP2019 data in the projections for Table 29.

b. Entitlements statistics; other relevant statistics

The entitlement statistics for 2018 are taken from the national accounts (government accounts) and Federal Pensions Service. Other statistics, such as on social contributions and transfers between schemes, come from the national accounts, Federal Pensions Service and National Institute for the Social Security of the Self-employed.

4. Reforms incorporated in the model

None.

5. Specific assumptions

a. How are careers modelled?

Future career evolution is projected by the microsimulation model MIDAS, using the projection of the aggregate numbers of civil servants by age and gender provided by the meso-economic model MALTESE, as well as behavioural equations for transitions between states.

b. How are survivors' pensions calculated?

- Wage-earners

After the death of the spouse who either earned a wage or received a replacement income (pension included) in the wage earners' scheme, the surviving spouse is entitled to a survivor's pension if some conditions are met. The most important is the minimum age. If the surviving partner has reached a minimum age, she/he will receive the survivor's pension. If she/he is younger than this minimum age, she/he will not receive a survivor's pension but a transitional benefit. The age condition was 46.5 in 2018 and will be gradually increased to 50 by 2025.

A survivor's pension represents 80% of the deceased person's retirement pension, computed at the family rate (which means 80% of 75%, equivalent to 60% of the reference wage), or, if she/he was still working, at 80% of the retirement pension she/he would have had if she/he had work until the legal age of retirement.

- Self-employed

After the death of the spouse who was self-employed, the surviving spouse is entitled to a survivor's pension if some conditions are met. The most important is the minimum age. If the surviving partner has reached a minimum age, she/he will receive a survivor's pension. If she/he is younger than this minimum age, she/he will not receive a survivor's pension but a transitional benefit. The age condition was 46.5 in 2018 and will be gradually increased to 50 by 2025.

The calculation takes into account the career of the deceased person and his/her business income.

c. How is the retirement age modelled over time?

The statutory retirement age in Belgium is currently 65 (both men and women and all pension schemes). It will increase from 65 to 66 by 2025 and further to 67 by 2030.

d. Other specific features of the model

6. Any other comments

It is possible for a wage earner or self-employed to start working for a European institution and to have his pension rights accrued in the Belgian pension scheme recognised by the European institution or its pension fund. The corresponding amount of contributions will then be transferred from the Belgian pension scheme towards the European pension scheme. These transfers explain why row 6 does not balance for the total economy.
